Package 'ShinyItemAnalysis'

July 21, 2025

Type Package

Title Test and Item Analysis via Shiny

Version 1.5.5

Date 2025-07-10

Description Package including functions and interactive shiny application for the psychometric analysis of educational tests, psychological assessments, health-related and other types of multi-item measurements, or ratings from multiple raters.

License GPL-3

`ShinyItemAnalysis-package`

ShinyItemAnalysis: Test and Item Analysis via Shiny

Description

The `ShinyItemAnalysis` package contains an interactive Shiny application for the psychometric analysis of educational tests, psychological assessments, health-related and other types of multi-item measurements, or ratings from multiple raters, which can be accessed using function `startShinyItemAnalysis()`. The shiny application covers a broad range of psychometric methods and offers data examples, model equations, parameter estimates, interpretation of results, together with a selected R code, and is therefore suitable for teaching psychometric concepts with R. It also allows the users to upload and analyze their own data and to automatically generate analysis reports in PDF or HTML.

Besides, the package provides its own functions for test and item analysis within classical test theory framework (e.g., functions `gDiscrim()`, `ItemAnalysis()`, `DistractorAnalysis()`, or `DDplot()`), using various regression models (e.g., `plotCumulative()`, `plotAdjacent()`, `plotMultinomial()`, or `plotDIFLogistic()`), and under IRT framework (e.g., `ggWrightMap()`, or `plotDIFirt()`).

Package also contains several demonstration datasets including the `HCI` dataset from the book by Martinkova and Hladka (2023), and from paper by Martinkova and Drabinova (2018).

Functions

- `startShinyItemAnalysis()`
- `DDplot()`
- `DistractorAnalysis()`
- `plotDistractorAnalysis()`

- fa_parallel()
- gDiscrim()
- ggWrightMap()
- ICCrestricted()
- ItemAnalysis()
- blis()
- plotAdjacent(), plotCumulative(), plotMultinomial()
- plotDIFirt(), plotDIFLogistic()
- plot_corr()
- recode_nr()

Datasets

- AIBS()
- Anxiety()
- AttitudesExpulsion()
- BFI2()
- CLoSEread6()
- CZmatura()
- CZmaturaS()
- dataMedical()
- dataMedicalgraded()
- dataMedicalkey()
- dataMedicaltest()
- HCI()
- HCIdata()
- HCIgrads()
- HCIkey()
- HCIlong()
- HCIprepost()
- HCItest()
- HCItestretest()
- HeightInventory()
- LearningToLearn()
- MSATB()
- MSclinical()
- NIH()
- TestAnxietyCor()

`AIBS` *AIBS grant peer review scoring dataset*

Description

The `AIBS` dataset (Gallo, 2020) comes from the scientific peer review facilitated by the American Institute of Biological Sciences (AIBS) of biomedical applications from and intramural collaborative biomedical research program for 2014–2017. For each proposal, three assigned individual reviewers were asked to provide scores and commentary for the following application criteria: Innovation, Approach/Feasibility, Investigator, and Significance (Impact added as scored criterion in 2014). Each of these criteria is scored on a scale from 1.0 (best) to 5.0 (worst) with a 0.1 gradation, as well as an overall score (1.0–5.0 with a 0.1 gradation). Asynchronous discussion was allowed, although few scores changed post-discussion. The data includes reviewers' self-reported expertise scores (1/2/3, 1 is high expertise) relative to each proposal reviewed, and reviewer / principal investigator demographics. A total of 72 applications ("Standard" or "Pilot") were reviewed in 3 review cycles. The success rate was 34–38 %. Application scores indicate where each application falls among all practically possible applications in comparison with the ideal standard of quality from a perfect application. The dataset was used by Erosheva et al. (2021a) to demonstrate issues of inter-rater reliability in case of restricted samples. For details, see Erosheva et al. (2021b).

Usage

```
AIBS
```

Format

`AIBS` is a `data.frame` consisting of 216 observations on 25 variables. Data describes 72 proposals with 3 ratings each.

ID Proposal ID.

Year Year of the review.

PropType Proposal type; `"Standard"` or `"Pilot"`.

PIID Anonymized ID of principal investigator (PI).

PIOrgType PI's organization type.

PIGender PI's gender membership; `"1"` females, `"2"` males.

PIRank PI's rank; `"3"` full professor, `"1"` assistant professor.

PIDegree PI's degree; `"1"` PhD, `"2"` MD, `"3"` PhD/MD.

Innovation Innovation score.

Approach Approach score.

Investig Investigator score.

Signif Significance score.

Impact Impact score.

Score Scientific merit (overall) score.

ScoreAvg Average of the three overall scores from three different reviewers.

ScoreAvgAdj Average of the three overall scores from three different reviewers, increased by multiple of 0.001 of the worst score.

ScoreRank Project rank calculated based on `ScoreAvg`.

ScoreRankAdj Project rank calculated based on `ScoreAvgAdj`.

RevID Reviewer's ID.

RevExp Reviewer's experience.

RevInst Reviewer's institution; `"1"` academia, `"2"` government.

RevGender Reviewer's gender; `"1"` females, `"2"` males.

RevRank Reviewer's rank; `"3"` full professor, `"1"` assistant professor.

RevDegree Reviewer's degree; `"1"` PhD, `"2"` MD, `"3"` PhD/MD.

RevCode Reviewer code (`"A"`, `"B"`, `"C"`) in the original wide dataset.

`Anxiety` *PROMIS Anxiety Scale Dataset*

Description

The data contains responses from 766 people sampled from a general population to the PROMIS Anxiety scale (http://www.nihpromis.org) composed of 29 Likert-type questions with a common rating scale (1 = Never, 2 = Rarely, 3 = Sometimes, 4 = Often, and 5 = Always).

Usage

```
Anxiety
```

Format

A data frame with 766 observations on the following 32 variables.

`age` 0 = younger than 65 and 1 = 65 and older

`gender` 0 = Male and 1 = Female

`education` 0 = some college or higher and 1 = high school or lower

`R1` I felt fearful

`R2` I felt frightened

`R3` It scared me when I felt nervous

`R4` I felt anxious

`R5` I felt like I needed help for my anxiety

`R6` I was concerned about my mental health

`R7` I felt upset

`R8` I had a racing or pounding heart

`R9` I was anxious if my normal routine was disturbed

`R10` I had sudden feelings of panic

`R11` I was easily startled

`R12` I had trouble paying attention

`R13` I avoided public places or activities

`R14` I felt fidgety

`R15` I felt something awful would happen

`R16` I felt worried

`R17` I felt terrified

`R18` I worried about other people's reactions to me

`R19` I found it hard to focus on anything other than my anxiety

`R20` My worries overwhelmed me

`R21` I had twitching or trembling muscles

`R22` I felt nervous

`R23` I felt indecisive

`R24` Many situations made me worry

`R25` I had difficulty sleeping

`R26` I had trouble relaxing

`R27` I felt uneasy

`R28` I felt tense

`R29` I had difficulty calming down

`score` Total score.

`zscore` Standardized total score.

`AttitudesExpulsion` *Attitudes towards the Expulsion of the Sudeten Germans (dataset)*

Description

Dataset from Kolek et al. (2021) study investigating a video game's effects on implicit and explicit attitudes towards depicted historical events in the short- and long-term. As an intervention tool, a serious game *Czechoslovakia 38–89: Borderlands* was utilized that deals with the expulsion of the Sudeten Germans from the former Czechoslovakia after the WWII. Data consists responses from 145 adults from two groups (experimental and control group) on number of multi-item measurements.

Usage

```
AttitudesExpulsion
```

Format

A *data.frame* with 145 rows and 239 variables:

ID anonymous identifier

Group C = control or E = experimental group

Gender *factor*, `male` or `female`

GenderF *integer*, 1 = female

Merkel effect of Merkel speech between the posttest and the delayed posttest, range 0–5, where 0 stands for no effect, 5 for very significant effect

Sudety *factor*, N = not originally from Czech Borderlands; Y = originally from Czech Borderlands

Education *factor*, V = university; S = high school; Z = elementary school

Education123 *integer*, same as above, but coded as 3= university; 2= high school; 1= elementary school, meaning higher the number, higher the education

***PANASpn** total PANAS score of positive and negative affect scales

***PANASp** total PANAS score of positive affect scale

***PANASn** total PANAS score of negative affect scale

***Macro** Macro attitude measurement

***Micro** Micro attitude measurement

***IATeffect** Single-Category Implicit association test score

Items beginning with an asterisk have following prefixes in the actual dataset:

pre pretest

post immediate posttest

del one month delayed posttest

Post_Pre difference between posttest_pretest

Del_Post difference between delayed posttest and posttest

Source

Kolek, L., Šisler, V., Martinková, P., & Brom, C. (2021). Can video games change attitudes towards history? Results from a laboratory experiment measuring short- and long-term effects. *Journal of Computer Assisted Learning*, *1–22*. doi:10.1111/jcal.12575

BFI2 *BFI2 Dataset*

Description

BFI2 dataset (Hřebíčková et al., 2020) consists of responses of 1,733 respondents (1,003 females, 730 males) to Big Five Inventory 2 (BFI-2). It contains 60 ordinal items, vector of age, education, and vector of gender membership.

Usage

```
BFI2
```

Format

BFI2 is a data.frame consisting of 1,733 observations on 64 variables.

i1–i60 The BFI items, scored on Likert scale where 1 = Disagree strongly, 2 = Disagree a little, 3 = Neutral; no opinion, 4 = Agree a little, and 5 = Agree strongly. Some items were recoded so that all items are scored in the same direction, see Details.

Gender Gender membership, 0 = females, 1 = males.

Age Age in years.

Educ Education, 1 = Basic school, 2 = Secondary technical school, 3 = Secondary general school, 4 = Other secondary school, 5 = Tertiary professional school, 6 = Bachelor degree, 7 = Masters degree, 8 = PhD

Details

The items prefixed with i are item scores. Items are indicators of 5 latent personality factors/dimensions/domains, which are further broken down into so-called facets. The 5 personality domains are: N = Negative Emotionality, E = Extraversion, O = Open-Mindedness, C = Consciousness and A = Agreeability. These are further broken down into so-called facets, as shown in the following table:

Domain	Facet	Item numbers
E	Sociability (scb)	1, 16, 31, 46
E	Assertiveness (asr)	6, 21, 36, 51
E	Energy Level (enl)	11, 26, 41, 56
A	Compassion (cmp)	2, 17, 32, 47
A	Respectfulness (rsp)	7, 22, 37, 52
A	Trust (trs)	12, 27, 42, 57
C	Organization (org)	3, 18, 33, 48
C	Productiveness (prd)	8, 23, 38, 53
C	Responsibility (rsp)	13, 28, 43, 58
N	Anxiety (anx)	4, 19, 34, 49
N	Depression (dep)	9, 24, 39, 54
N	Emotional Volatility (emt)	14, 29, 44, 59

O	Intellectual Curiosity (int)	10, 25, 40, 55
O	Aesthetic Sensitivity (aes)	5, 20, 35, 50
O	Creative Imagination (crt)	15, 30, 45, 60

In the original instrument, some items are inversely oriented, i.e., the higher score means the lower latent trait. This was the case of items number 3, 4, 5, 8, 9, 11, 12, 16, 17, 22, 23, 24, 25, 26, 28, 29, 30, 31, 36, 37, 42, 44, 45, 47, 48, 49, 50, 51, 55, and 58. These **items have been recoded** for you, i.e., displayed is value of `6 - original score`.

In the sample code, alternative item names are provided. These item names can be used to decode the item domain, facet, item number, and whether it was recoded or not. For example, `iCorg03r` stands for recoded 3rd item (out of 60) from Consciousness domain and Organization facet.

Note

Thanks to Martina Hřebíčková for sharing this dataset.

BlisClass-class *BLIS S4 class*

Description

Extends `mirt`'s `SingleGroupClass` directly (meaning all `mirt` methods that work with that class will work with BlisClass too; make sure `mirt` is loaded).

Details

The purpose of the class is to have a custom `coef` method (see coef,BlisClass-method) dispatched and the original levels with correct response (as a `key` attribute) stored in the resulting fitted model.

Slots

`orig_levels` *list* of original levels with logical attribute `key`, which stores the information on which response (level) has been considered as correct. Note that levels not used in the original data are dropped.

See Also

Other BLIS/BLIRT related: `coef,BlisClass-method`, `fit_blis()`, `get_orig_levels()`, `nominal_to_int()`, `obtain_nrm_def()`, `print.blis_coefs()`

`CLoSEread6` *Czech Longitudinal Study in Education (CLoSE) - reading in 6th grade*

Description

`CLoSEread6` dataset consists of the dichotomously scored responses of 2,634 students (1,324 boys, 1,310 girls) on 19 multiple-choice items in a test of reading skills, version B, taken in the 6th grade. Item responses were dichotomized: 1 point was awarded only if the answer was fully correct and 0 if it was not (Greger, Straková, & Martinková, 2022; Martinková, Hladká, & Potužníková, 2020; Hladká, Martinková, & Magis, 2023)

Usage

```
CLoSEread6
```

Format

`CLoSEread6` is a `data.frame` consisting of 2,634 observations on the 20 variables.

Q6B_1-Q6B_19 Dichotomously scored items of the test on reading skills.

gender Gender membership, `"0"` boys, `"1"` girls.

---

coef,BlisClass-method *Get Coefficients from a fitted BLIS model*

Description

Extracts item parameters from fitted BLIS model. For BLIRT parametrization, use `IRTpars = TRUE` in your function call. Contrary to mirt::coef,SingleGroupClass-method, response category labels can be displayed in the output using `labels = TRUE`. On top of that, as BLIS/BLIRT parametrizations utilize the information of correct response category, you can denote these in the output with `mark_correct = TRUE`.

Usage

```
## S4 method for signature 'BlisClass'
coef(
  object,
  ...,
  CI = 0.95,
  printSE = FALSE,
  IRTpars = FALSE,
  simplify = FALSE,
  labels = FALSE,
  mark_correct = labels
)
```

Arguments

`object`	*object of class BlisClass*, model fitted via `fit_blis()` or `blis()`.
`...`	Additional arguments. Not utilized at the moment.
`CI`	*numeric*, a width of the confidence intervals.
`printSE`	*logical*, print standard errors instead of CI? Defaults to `FALSE`.
`IRTpars`	*logical*, convert slope intercept parameters into IRT parameters (i.e. BLIRT)? Defaults to `FALSE`.

`simplify`	*logical*, return coefficients as a matrix, instead of list? Defaults to `FALSE`. *Not implemented yet.*
`labels`	*logical*, if `TRUE`, show response labels (e.g. "A", "B", "C") instead of response numeric indices (e.g. 0, 1, 2). Defaults to `FALSE`.
`mark_correct`	*logical*, mark the correct response with an asterisk symbol. Applicable only if `labels` is `TRUE` (in which case, `mark_correct` defaults to `TRUE`).

Value

List of item coefficients of S3 class `blis_coefs`, so the resulting output of `coef()` call is formatted to display only first 3 digits (you can opt for different rounding via the print.blis_coefs method, see the examples). Note that the list-object returned invisibly has the raw coefficients stored in it.

See Also

Other BLIS/BLIRT related: `BlisClass-class`, `fit_blis()`, `get_orig_levels()`, `nominal_to_int()`, `obtain_nrm_def()`, `print.blis_coefs()`

Examples

```
fitted_blis <- fit_blis(HCItest[, 1:20], HCIkey)

# BLIS coefs
coef(fitted_blis)

# BLIRT coefs
coef(fitted_blis, IRTpars = TRUE)

# store raw coefs
blis_coefs <- coef(fitted_blis)

# print coefs rounded to 2 digits
print(blis_coefs, digits = 2)
```

`CZmatura` *CZmatura dataset*

Description

The `CZmatura` dataset comes from matura exam in mathematics. The exam was assigned in 2019 to students from Grade 13, at the end of their secondary education. Original data available from https://cermat.gov.cz/.

Usage

```
CZmatura
```

Format

`CZmatura` is a `data.frame` consisting of 15,702 observations on 75 variables.

SchType School type code.

FirstAtt First attempt; `"1"` yes, `"0"` no.

SchTypeGY School type gymnasium; `"1"` yes, `"0"` no.

o1 – o26.2 Item answers.

b1 – b26 Scored item answers.

Total Total score, calculated as sum of item scores (0 - 50).

IRTscore Score estimated from GPCM/2PL model.

IRTscoreSE SE of score estimated from GPCM/2PL model.

See Also

`CZmaturaS()`

`CZmaturaS` *CZmatura dataset - sample*

Description

The `CZmaturaS` dataset comes from a matura exam in mathematics. The exam was assigned in 2019 to students in Grade 13, at the end of their secondary education. This is a random sample of 2,000 students from a total of 15,702. Original data available from https://cermat.gov.cz/.

Usage

```
CZmaturaS
```

Format

`CZmatura` is a `data.frame` consisting of 2,000 observations on 75 variables.

SchType School type code.

FirstAtt First attempt; `"1"` yes, `"0"` no.

SchTypeGY School type gymnasium; `"1"` yes, `"0"` no.

o1 – o26.2 Item answers.

b1 – b26 Scored item answers.

Total Total score, calculated as sum of item scores (0 - 50).

IRTscore Score estimated from GPCM/2PL model.

IRTscoreSE SE of score estimated from GPCM/2PL model.

`CZmatura()`

`dataMedical` *Dichotomous dataset of admission test to medical school*

Description

The `dataMedical` dataset consists of the responses of 2,392 subjects (750 males, 1,633 females and 9 subjects without gender specification) to admission test to a medical school. It contains 100 items. A correct answer is coded as `"1"` and incorrect answer as `"0"`. Missing answers were evaluated as incorrect, i.e. `"0"`.

Usage

```
dataMedical
```

Format

A `dataMedical` is a `data.frame` consisting of 2,392 observations on the following 102 variables.

X The first 100 columns represent dichotomously scored items of the test.

gender Variable describing gender; values `"0"` and `"1"` refer to males and females.

StudySuccess Criterion variable; value `"1"` means that student studies standardly, `"0"` otherwise (e.g., leaving or interrupting studies).

`dataMedicalgraded` *Graded dataset of admission test to medical school*

Description

The `dataMedicalgraded` dataset consists of the responses of 2,392 subjects (750 males, 1,633 females and 9 subjects without gender specification) to multiple-choice admission test to a medical school. It contains 100 items. Each item is graded with 0 to 4 points. Maximum of 4 points were set if all correct answers and none of incorrect answers were selected.

Usage

```
dataMedicalgraded
```

Format

A `dataMedicalgraded` is a `data.frame` consisting of 2,392 observations on the following 102 variables.

X The first 100 columns represent ordinal item scores of the test.

gender Variable describing gender; values `"0"` and `"1"` refer to males and females.

StudySuccess Criterion variable; value `"1"` means that student studies standardly, `"0"` otherwise (e.g., leaving or interrupting studies).

dataMedicaltest *Dataset of admission test to medical school*

Description

The dataMedicaltest dataset consists of the responses of 2,392 subjects (750 males, 1,633 females and 9 subjects without gender specification) to multiple-choice admission test to a medical school. It contains 100 items, possible answers were A, B, C, D, while any combination of these can be correct.

Usage

```
dataMedicaltest
```

Format

A `dataMedicaltest` is a `data.frame` consisting of 2,392 observations on the following 102 variables.

X The first 100 columns represent items answers.

gender Variable describing gender; values `"0"` and `"1"` refer to males and females.

StudySuccess Criterion variable; value `"1"` means that student studies standardly, `"0"` otherwise (e.g., leaving or interrupting studies).

`DDplot` *Plot difficulties and discriminations/item validity*

Description

Plots difficulty and (generalized) discrimination or criterion validity for items of the multi-item measurement test using the **ggplot2** package. Difficulty and discrimination/validity indices are plotted for each item, items are ordered by their difficulty.

Usage

```
DDplot(
  Data,
  item.names,
  discrim = "ULI",
  k = 3,
  l = 1,
  u = 3,
  maxscore,
  minscore,
  bin = FALSE,
  cutscore,
```

```
  average.score = FALSE,
  thr = 0.2,
  criterion = "none",
  val_type = "simple",
  data
)
```

Arguments

Data	numeric: binary or ordinal data matrix or data.frame which rows represent examinee answers (1 correct, 0 incorrect, or ordinal item scores) and columns correspond to the items.
item.names	character: the names of items. If not specified, the names of Data columns are used.
discrim	character: type of discrimination index to be calculated. Possible values are "ULI" (default), "RIT", "RIR", and "none". See **Details**.
k	numeric: number of groups to which data may be divided by the total score to estimate discrimination using discrim = "ULI". Default value is 3. See **Details**.
l	numeric: lower group. Default value is 1. See **Details**.
u	numeric: upper group. Default value is 3. See **Details**.
maxscore	numeric: maximal scores of items. If single number is provided, the same maximal score is used for all items. If missing, vector of achieved maximal scores is calculated and used in calculations.
minscore	numeric: minimal scores of items. If single number is provided, the same maximal score is used for all items. If missing, vector of achieved maximal scores is calculated and used in calculations.
bin	logical: should the ordinal data be binarized? Default value is FALSE. In case that bin = TRUE, all values of Data equal or greater than cutscore are marked as 1 and all values lower than cutscore are marked as 0.
cutscore	numeric: cut-score used to binarize Data. If numeric, the same cut-score is used for all items. If missing, vector of maximal scores is used in calculations.
average.score	logical: should average score of the item be displayed instead of difficulty? Default value is FALSE. See **Details**.
thr	numeric: value of discrimination threshold. Default value is 0.2. With thr = NULL, no horizontal line is displayed in the plot.
criterion	numeric or logical vector: values of criterion. If supplied, disrim argument is ignored and item-criterion correlation (validity) is displayed instead. Default value is "none".
val_type	character: criterion validity measure. Possible values are "simple" (correlation between item score and validity criterion; default) and "index" (item validity index calculated as cor(item, criterion) * sqrt(((N - 1) / N) * var(item)), where N is number of respondents, see Allen & Yen, 1979, Ch. 6.4, for details). The argument is ignored if user does not supply any criterion.
data	deprecated. Use argument Data instead.

Details

Discrimination is calculated using method specified in `discrim`. Default option `"ULI"` calculates difference in ratio of correct answers in upper and lower third of students. `"RIT"` index calculates correlation between item score and test total score. `"RIR"` index calculates correlation between item score and total score for the rest of the items. With option `"none"`, only difficulty is displayed.

`"ULI"` index can be generalized using arguments `k`, `l` and `u`. Generalized ULI discrimination is then computed as follows: The function takes data on individuals, computes their total test score and then divides individuals into `k` groups. The lower and upper group are determined by `l` and `u` parameters, i.e. l-th and u-th group where the ordering is defined by increasing total score.

For ordinal data, difficulty is defined as a relative score:

```
(achieved - minimal)/(maximal - minimal)
```

Minimal score can be specified by `minscore`, maximal score can be specified by `maxscore`. Average score of items can be displayed with argument `average.score = TRUE`. Note that for binary data difficulty estimate is the same as average score of the item.

Note that all correlations are estimated using Pearson correlation coefficient.

## End(Not run)
```

`DistractorAnalysis` *Distractor analysis*

Description

Performs distractor analysis for each item and optional number of groups.

Usage

```
DistractorAnalysis(
  Data,
  key,
  item = "all",
  p.table = FALSE,
  num.groups = 3,
  criterion = NULL,
  crit.discrete = FALSE,
  cut.points,
  data,
  matching,
  match.discrete
)
```

Arguments

Data	character: data matrix or data.frame with rows representing unscored item responses from a multiple-choice test and columns corresponding to the items.
key	character: answer key for the items. The key must be a vector of the same length as ncol(Data). In case it is not provided, criterion needs to be specified.
item	numeric or character: either character "all" to apply for all items (default), or a vector of item names (column names of Data), or item identifiers (integers specifying the column number).
p.table	logical: should the function return the proportions? If FALSE (default), the counts are returned.
num.groups	numeric: number of groups to which are the respondents split.
criterion	numeric: numeric vector. If not provided, total score is calculated and distractor analysis is performed based on it.
crit.discrete	logical: is criterion discrete? Default value is FALSE. See details.
cut.points	numeric: numeric vector specifying cut points of criterion. See details.
data	deprecated. Use argument Data instead.
matching	deprecated. Use argument criterion instead.
match.discrete	deprecated. Use argument crit.discrete instead.

Details

This function is an adapted version of the distractor.analysis() function from **CTT** package. In case that no criterion is provided, the scores are calculated using the item Data and key. The respondents are by default split into the num.groups-quantiles and the number (or proportion) of respondents in each quantile is reported with respect to their answers. In case that criterion is discrete (crit.discrete = TRUE), criterion is split based on its unique levels. Other cut points can be specified via cut.points argument.

## End(Not run)
```

EPIA *The Eysenck Personality Inventory Impulsivity Subscale*

Description

The data came from a published study and was kindly provided by Dr. Ferrando. A group of 1,033 undergraduate students were asked to check on a 112 mm line segment with two end points (almost

never, almost always) using their own judgment for the five items taken from the Spanish version of the EPI-A impulsivity subscale. The direct item score was the distance in mm of the check mark from the left end point (Ferrando, 2002).

Usage

```
EPIA
```

Format

A data frame with 1033 observations on the following 5 variables. The sixth variable is a total score (i.e. the sum of the items).

`Item 1` Longs for excitement

`Item 2` Does not stop and think things over before doing anything

`Item 3` Often shouts back when shouted at

`Item 4` Likes doing things in which he/she has to act quickly

`Item 5` Tends to do many things at the same time

`score` Total score for the aforementioned items

Source

Reexport from `EstCRM` package with added total scores.

`fa_parallel` *Conduct Parallel Analysis*

Description

Computes the eigenvalues of the sample correlation matrix and the eigenvalues obtained from a random correlation matrix for which no factors/components are assumed. By default, the function utilizes a modified Horn's (1965) method, which – instead of mean – uses 95th percentile of each item eigenvalues sampling distribution as a threshold to find the optimal number of factors/components.

Usage

```
fa_parallel(
  Data,
  cor = "pearson",
  n_obs = NULL,
  method = "pca",
  threshold = "quantile",
  p = 0.95,
  n_iter = 20,
  plot = TRUE,
  show_kaiser = TRUE,
  fm = "minres",
  use = "pairwise",
  ...
)
```

Arguments

`Data`	*data.frame* or *matrix*, dataset (where rows are observations and columns items) or correlation matrix (recognized automatically).
`cor`	*character*, how to calculate the correlation matrix of the real data. Can be either `pearson` (default), `tetrachoric` or `polychoric`. Unambiguous abbreviations accepted.
`n_obs`	*integer*, in case you provided the correlation matrix directly as the input, you have to provide the number of observations in the original dataset.
`method`	*character*, either `fa`, `pca`, or `both` (the default). Which method to use for the eigenvalues simulation and computation.
`threshold`	*character*, whether to use traditionall Horn's method or more recent and well-performing quantile one. Either `mean` or `quantile` (default). Can be abbreviated.
`p`	*numeric* (0–1), probability for which the sample quantile is produced. Defaults to `.95`. Ignored if `threshold = "mean"`.
`n_iter`	*integer*, number of iterations, i.e. the number of zero-factor multivariate normal distributions to sample. Defaults to `20`.
`plot`	*logical*, if `TRUE` (the default), show the plot along with the function results. To create the plot from the resulting object afterwards, call `plot()`.
`show_kaiser`	*logical*, whether to show Kaiser boundary in the plot (the default) or not.
`fm`	*character*, factoring method. See `psych::fa()` from the package `psych::psych()`.
`use`	an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
`...`	Arguments passed on to `psych::polychoric` `correct` Correction value to use to correct for continuity in the case of zero entry cell for tetrachoric, polychoric, polybi, and mixed.cor. See the examples for the effect of correcting versus not correcting for continuity.

`smooth` if TRUE and if the tetrachoric/polychoric matrix is not positive definite, then apply a simple smoothing algorithm using cor.smooth

`global` When finding pairwise correlations, should we use the global values of the tau parameter (which is somewhat faster), or the local values (global=FALSE)? The local option is equivalent to the polycor solution, or to doing one correlation at a time. global=TRUE borrows information for one item pair from the other pairs using those item's frequencies. This will make a difference in the presence of lots of missing data. With very small sample sizes with global=FALSE and correct=TRUE, the function will fail (for as yet undetermined reasons.

`weight` A vector of length of the number of observations that specifies the weights to apply to each case. The NULL case is equivalent of weights of 1 for all cases.

`progress` Show the progress bar (if not doing multicores)

`ML` ML=FALSE do a quick two step procedure, ML=TRUE, do longer maximum likelihood — very slow! Deprecated

`delete` Cases with no variance are deleted with a warning before proceeding.

`max.cat` The maximum number of categories to bother with for polychoric.

Details

Horn proposed a solution to the problem of optimal factor number identification using an approach based on a Monte Carlo simulation.

First, several (20 by default) zero-factor p-variate normal distributions (where `p` is the number of columns) are obtained, and $p \times p$ correlation matrices are computed for them. Eigenvalues of each matrix is then calculated in order to get an eigenvalues sampling distribution for each simulated variable.

Traditionally, Horn obtains an average of each sampling distribution and these averages are used as a threshold which is compared with eigenvalues of the original, real data. However, *usage of the mean was later disputed* by Buja & Eyuboglu (1992), and 95th percentile of eigenvalues sampling distribution was suggested as a more accurate threshold. This, more recent method is used by default in the function.

Value

An object of class `data.frame` and `sia_parallel`. Can be plotted using `plot()`.

fit_blis *Fit Baseline-category Logit Intercept-Slope (BLIS) model on nominal data*

Description

`blis` fits the IRT Nominal Response Model to data from multiple-choice tests, while accounting for the correct answer and treating this option as a baseline in this baseline-category logit model. The intercept-slope parametrization in BLIS can be converted to IRT (difficulty-discrimination) parametrization (BLIRT).

Usage

```
fit_blis(Data, key, ...)

blis(Data, key, ...)
```

Arguments

`Data`	*data.frame* or *tibble* with all columns being factors. Support for *matrix* is limited and behavior not guaranteed.
`key`	A single-column `data.frame`, (**not** matrix) `tibble` or - preferably - a factor vector of levels considered as correct responses.
`...`	Arguments passed on to `mirt::mirt`
	`SE` logical; estimate the standard errors by computing the parameter information matrix? See `SE.type` for the type of estimates available

`covdata` a data.frame of data used for latent regression models

`formula` an R formula (or list of formulas) indicating how the latent traits can be regressed using external covariates in `covdata`. If a named list of formulas is supplied (where the names correspond to the latent trait names in `model`) then specific regression effects can be estimated for each factor. Supplying a single formula will estimate the regression parameters for all latent traits by default

`itemdesign` a `data.frame` with rows equal to the number of items and columns containing any item-design effects. If items should be included in the design structure (i.e., should be left in their canonical structure) then fewer rows can be used, however the `rownames` must be defined and matched with `colnames` in the `data` input. The item design matrix is constructed with the use of `item.formula`. Providing this input will fix the associated `'d'` intercepts to 0, where applicable

`item.formula` an R formula used to specify any intercept decomposition (e.g., the LLTM; Fischer, 1983). Note that only the right-hand side of the formula is required for compensatory models.

For non-compensatory `itemtypes` (e.g., `'PC1PL'`) the formula must include the name of the latent trait in the left hand side of the expression to indicate which of the trait specification should have their intercepts decomposed (see MLTM; Embretson, 1984)

`SE.type` type of estimation method to use for calculating the parameter information matrix for computing standard errors and `wald` tests. Can be:

- `'Richardson'`, `'forward'`, or `'central'` for the numerical Richardson, forward difference, and central difference evaluation of observed Hessian matrix
- `'crossprod'` and `'Louis'` for standard error computations based on the variance of the Fisher scores as well as Louis' (1982) exact computation of the observed information matrix. Note that Louis' estimates can take a long time to obtain for large sample sizes and long tests
- `'sandwich'` for the sandwich covariance estimate based on the `'crossprod'` and `'Oakes'` estimates (see Chalmers, 2018, for details)
- `'sandwich.Louis'` for the sandwich covariance estimate based on the `'crossprod'` and `'Louis'` estimates
- `'Oakes'` for Oakes' (1999) method using a central difference approximation (see Chalmers, 2018, for details)
- `'SEM'` for the supplemented EM (disables the `accelerate` option automatically; EM only)
- `'Fisher'` for the expected information, `'complete'` for information based on the complete-data Hessian used in EM algorithm
- `'MHRM'` and `'FMHRM'` for stochastic approximations of observed information matrix based on the Robbins-Monro filter or a fixed number of MHRM draws without the RM filter. These are the only options supported when `method = 'MHRM'`
- `'numerical'` to obtain the numerical estimate from a call to `optim` when `method = 'BL'`

Note that both the 'SEM' method becomes very sensitive if the ML solution has has not been reached with sufficient precision, and may be further sensitive if the history of the EM cycles is not stable/sufficient for convergence of the respective estimates. Increasing the number of iterations (increasing NCYCLES and decreasing TOL, see below) will help to improve the accuracy, and can be run in parallel if a mirtCluster object has been defined (this will be used for Oakes' method as well). Additionally, inspecting the symmetry of the ACOV matrix for convergence issues by passing technical = list(symmetric = FALSE) can be helpful to determine if a sufficient solution has been reached

method a character object specifying the estimation algorithm to be used. The default is 'EM', for the standard EM algorithm with fixed quadrature, 'QMCEM' for quasi-Monte Carlo EM estimation, or 'MCEM' for Monte Carlo EM estimation. The option 'MHRM' may also be passed to use the MH-RM algorithm, 'SEM' for the Stochastic EM algorithm (first two stages of the MH-RM stage using an optimizer other than a single Newton-Raphson iteration), and 'BL' for the Bock and Lieberman approach (generally not recommended for longer tests).

The 'EM' is generally effective with 1-3 factors, but methods such as the 'QMCEM', 'MCEM', 'SEM', or 'MHRM' should be used when the dimensions are 3 or more. Note that when the optimizer is stochastic the associated SE.type is automatically changed to SE.type = 'MHRM' by default to avoid the use of quadrature

optimizer a character indicating which numerical optimizer to use. By default, the EM algorithm will use the 'BFGS' when there are no upper and lower bounds box-constraints and 'nlminb' when there are.

Other options include the Newton-Raphson ('NR'), which can be more efficient than the 'BFGS' but not as stable for more complex IRT models (such as the nominal or nested logit models) and the related 'NR1' which is also the Newton-Raphson but consists of only 1 update that has been coupled with RM Hessian (only applicable when the MH-RM algorithm is used). The MH-RM algorithm uses the 'NR1' by default, though currently the 'BFGS', 'L-BFGS-B', and 'NR' are also supported with this method (with fewer iterations by default) to emulate stochastic EM updates. As well, the 'Nelder-Mead' and 'SANN' estimators are available, but their routine use generally is not required or recommended.

Additionally, estimation subroutines from the Rsolnp and nloptr packages are available by passing the arguments 'solnp' and 'nloptr', respectively. This should be used in conjunction with the solnp_args and nloptr_args specified below. If equality constraints were specified in the model definition only the parameter with the lowest parnum in the pars = 'values' data.frame is used in the estimation vector passed to the objective function, and group hyper-parameters are omitted. Equality an inequality functions should be of the form function(p, optim_args), where optim_args is a list of internally parameters that largely can be ignored when defining constraints (though use of browser() here may be helpful)

dentype type of density form to use for the latent trait parameters. Current options include

- 'Gaussian' (default) assumes a multivariate Gaussian distribution with an associated mean vector and variance-covariance matrix
- 'empiricalhist' or 'EH' estimates latent distribution using an empirical histogram described by Bock and Aitkin (1981). Only applicable for unidimensional models estimated with the EM algorithm. For this option, the number of cycles, TOL, and quadpts are adjusted accommodate for less precision during estimation (namely: TOL = 3e-5, NCYCLES = 2000, quadpts = 121)
- 'empiricalhist_Woods' or 'EHW' estimates latent distribution using an empirical histogram described by Bock and Aitkin (1981), with the same specifications as in dentype = 'empiricalhist', but with the extrapolation-interpolation method described by Woods (2007). NOTE: to improve stability in the presence of extreme response styles (i.e., all highest or lowest in each item) the technical option zeroExtreme = TRUE may be required to down-weight the contribution of these problematic patterns
- 'Davidian-#' estimates semi-parametric Davidian curves described by Woods and Lin (2009), where the # placeholder represents the number of Davidian parameters to estimate (e.g., 'Davidian-6' will estimate 6 smoothing parameters). By default, the number of quadpts is increased to 121, and this method is only applicable for unidimensional models estimated with the EM algorithm

Note that when itemtype = 'ULL' then a log-normal(0,1) density is used to support the unipolar scaling

constrain a list of user declared equality constraints. To see how to define the parameters correctly use pars = 'values' initially to see how the parameters are labeled. To constrain parameters to be equal create a list with separate concatenated vectors signifying which parameters to constrain. For example, to set parameters 1 and 5 equal, and also set parameters 2, 6, and 10 equal use constrain = list(c(1,5), c(2,6,10)). Constraints can also be specified using the mirt.model syntax (recommended)

calcNull logical; calculate the Null model for additional fit statistics (e.g., TLI)? Only applicable if the data contains no NA's and the data is not overly sparse

draws the number of Monte Carlo draws to estimate the log-likelihood for the MH-RM algorithm. Default is 5000

survey.weights a optional numeric vector of survey weights to apply for each case in the data (EM estimation only). If not specified, all cases are weighted equally (the standard IRT approach). The sum of the survey.weights must equal the total sample size for proper weighting to be applied

quadpts number of quadrature points per dimension (must be larger than 2). By default the number of quadrature uses the following scheme: switch(as.character(nfact), '1'=61, '2'=31, '3'=15, '4'=9, '5'=7, 3). However, if the method input is set to 'QMCEM' and this argument is left blank then the default number of quasi-Monte Carlo integration nodes will be set to 5000 in total

TOL convergence threshold for EM or MH-RM; defaults are .0001 and .001. If SE.type = 'SEM' and this value is not specified, the default is set to 1e-5.

To evaluate the model using only the starting values pass TOL = NaN, and to evaluate the starting values without the log-likelihood pass TOL = NA

gpcm_mats a list of matrices specifying how the scoring coefficients in the (generalized) partial credit model should be constructed. If omitted, the standard gpcm format will be used (i.e., seq(0, k, by = 1) for each trait). This input should be used if traits should be scored different for each category (e.g., matrix(c(0:3, 1,0,0,0), 4, 2) for a two-dimensional model where the first trait is scored like a gpcm, but the second trait is only positively indicated when the first category is selected). Can be used when itemtypes are 'gpcm' or 'Rasch', but only when the respective element in gpcm_mats is not NULL

grsm.block an optional numeric vector indicating where the blocking should occur when using the grsm, NA represents items that do not belong to the grsm block (other items that may be estimated in the test data). For example, to specify two blocks of 3 with a 2PL item for the last item: grsm.block = c(rep(1,3), rep(2,3), NA). If NULL the all items are assumed to be within the same group and therefore have the same number of item categories

rsm.block same as grsm.block, but for 'rsm' blocks

monopoly.k a vector of values (or a single value to repeated for each item) which indicate the degree of the monotone polynomial fitted, where the monotone polynomial corresponds to monopoly.k * 2 + 1 (e.g., monopoly.k = 2 fits a 5th degree polynomial). Default is monopoly.k = 1, which fits a 3rd degree polynomial

large a logical indicating whether unique response patterns should be obtained prior to performing the estimation so as to avoid repeating computations on identical patterns. The default TRUE provides the correct degrees of freedom for the model since all unique patterns are tallied (typically only affects goodness of fit statistics such as G2, but also will influence nested model comparison methods such as anova(mod1, mod2)), while FALSE will use the number of rows in data as a placeholder for the total degrees of freedom. As such, model objects should only be compared if all flags were set to TRUE or all were set to FALSE

Alternatively, if the collapse table of frequencies is desired for the purpose of saving computations (i.e., only computing the collapsed frequencies for the data onte-time) then a character vector can be passed with the arguement large = 'return' to return a list of all the desired table information used by mirt. This list object can then be reused by passing it back into the large argument to avoid re-tallying the data again (again, useful when the dataset are very large and computing the tabulated data is computationally burdensome). This strategy is shown below:

Compute organized data e.g., internaldat <- mirt(Science, 1, large = 'return')

Pass the organized data to all estimation functions e.g., mod <- mirt(Science, 1, large = internaldat)

GenRandomPars logical; generate random starting values prior to optimization instead of using the fixed internal starting values?

`accelerate` a character vector indicating the type of acceleration to use. Default is `'Ramsay'`, but may also be `'squarem'` for the SQUAREM procedure (specifically, the gSqS3 approach) described in Varadhan and Roldand (2008). To disable the acceleration, pass `'none'`

`verbose` logical; print observed- (EM) or complete-data (MHRM) log-likelihood after each iteration cycle? Default is TRUE

`solnp_args` a list of arguments to be passed to the `solnp::solnp()` function for equality constraints, inequality constraints, etc

`nloptr_args` a list of arguments to be passed to the `nloptr::nloptr()` function for equality constraints, inequality constraints, etc

`spline_args` a named list of lists containing information to be passed to the `bs` (default) and `ns` for each spline itemtype. Each element must refer to the name of the itemtype with the spline, while the internal list names refer to the arguments which are passed. For example, if item 2 were called 'read2', and item 5 were called 'read5', both of which were of itemtype 'spline' but item 5 should use the `ns` form, then a modified list for each input might be of the form:

`spline_args = list(read2 = list(degree = 4), read5 = list(fun = 'ns', knots = c(-2, 2)))`

This code input changes the `bs()` splines function to have a `degree = 4` input, while the second element changes to the `ns()` function with knots set a `c(-2, 2)`

`control` a list passed to the respective optimizers (i.e., `optim()`, `nlminb()`, etc). Additional arguments have been included for the `'NR'` optimizer: `'tol'` for the convergence tolerance in the M-step (default is `TOL/1000`), while the default number of iterations for the Newton-Raphson optimizer is 50 (modified with the `'maxit'` control input)

`technical` a list containing lower level technical parameters for estimation. May be:

NCYCLES maximum number of EM or MH-RM cycles; defaults are 500 and 2000

MAXQUAD maximum number of quadratures, which you can increase if you have more than 4GB or RAM on your PC; default 20000

theta_lim range of integration grid for each dimension; default is `c(-6, 6)`. Note that when `itemtype = 'ULL'` a log-normal distribution is used and the range is change to `c(.01, and 6^2)`, where the second term is the square of the `theta_lim` input instead

set.seed seed number used during estimation. Default is 12345

SEtol standard error tolerance criteria for the S-EM and MHRM computation of the information matrix. Default is 1e-3

symmetric logical; force S-EM/Oakes information matrix estimates to be symmetric? Default is TRUE so that computation of standard errors are more stable. Setting this to FALSE can help to detect solutions that have not reached the ML estimate

SEM_window ratio of values used to define the S-EM window based on the observed likelihood differences across EM iterations. The default is `c(0, 1 - SEtol)`, which provides nearly the very full S-EM window

(i.e., nearly all EM cycles used). To use the a smaller SEM window change the window to to something like `c(.9, .999)` to start at a point farther into the EM history

warn logical; include warning messages during estimation? Default is TRUE

message logical; include general messages during estimation? Default is TRUE

customK a numeric vector used to explicitly declare the number of response categories for each item. This should only be used when constructing mirt model for reasons other than parameter estimation (such as to obtain factor scores), and requires that the input data all have 0 as the lowest category. The format is the same as the `extract.mirt(mod, 'K')` slot in all converged models

customPriorFun a custom function used to determine the normalized density for integration in the EM algorithm. Must be of the form `function(Theta, Etable){...}`, and return a numeric vector with the same length as number of rows in `Theta`. The `Etable` input contains the aggregated table generated from the current E-step computations. For proper integration, the returned vector should sum to 1 (i.e., normalized). Note that if using the `Etable` it will be NULL on the first call, therefore the prior will have to deal with this issue accordingly

zeroExtreme logical; assign extreme response patterns a `survey.weight` of 0 (formally equivalent to removing these data vectors during estimation)? When `dentype = 'EHW'`, where Woods' extrapolation is utilized, this option may be required if the extrapolation causes expected densities to tend towards positive or negative infinity. The default is `FALSE`

customTheta a custom `Theta` grid, in matrix form, used for integration. If not defined, the grid is determined internally based on the number of `quadpts`

nconstrain same specification as the `constrain` list argument, however imposes a negative equality constraint instead (e.g., $a12 = -a21$, which is specified as `nconstrain = list(c(12, 21))`). Note that each specification in the list must be of length 2, where the second element is taken to be -1 times the first element

delta the deviation term used in numerical estimates when computing the ACOV matrix with the 'forward' or 'central' numerical approaches, as well as Oakes' method with the Richardson extrapolation. Default is 1e-5

parallel logical; use the parallel cluster defined by `mirtCluster`? Default is TRUE

storeEMhistory logical; store the iteration history when using the EM algorithm? Default is FALSE. When TRUE, use `extract.mirt` to extract

internal_constraints logical; include the internal constraints when using certain IRT models (e.g., 'grsm' itemtype). Disable this if you want to use special optimizers such as the solnp. Default is `TRUE`

gain a vector of two values specifying the numerator and exponent values for the RM gain function $(val1/cycle)^{v}al2$. Default is `c(0.10, 0.75)`

BURNIN number of burn in cycles (stage 1) in MH-RM; default is 150

SEMCYCLES number of SEM cycles (stage 2) in MH-RM; default is 100

MHDRAWS number of Metropolis-Hasting draws to use in the MH-RM at each iteration; default is 5

MHcand a vector of values used to tune the MH sampler. Larger values will cause the acceptance ratio to decrease. One value is required for each group in unconditional item factor analysis (`mixedmirt()` requires additional values for random effect). If null, these values are determined internally, attempting to tune the acceptance of the draws to be between .1 and .4

MHRM_SE_draws number of fixed draws to use when `SE=TRUE` and `SE.type = 'FMHRM'` and the maximum number of draws when `SE.type = 'MHRM'`. Default is 2000

MCEM_draws a function used to determine the number of quadrature points to draw for the `'MCEM'` method. Must include one argument which indicates the iteration number of the EM cycle. Default is `function(cycles) 500 + (cycles - 1)*2`, which starts the number of draws at 500 and increases by 2 after each full EM iteration

info_if_converged logical; compute the information matrix when using the MH-RM algorithm only if the model converged within a suitable number of iterations? Default is `TRUE`

logLik_if_converged logical; compute the observed log-likelihood when using the MH-RM algorithm only if the model converged within a suitable number of iterations? Default is `TRUE`

keep_vcov_PD logical; attempt to keep the variance-covariance matrix of the latent traits positive definite during estimation in the EM algorithm? This generally improves the convergence properties when the traits are highly correlated. Default is `TRUE`

Details

For the details on `coef` method dispatched for fitted BLIS model, see coef,BlisClass-method. To get more on the class, see BlisClass.

Value

Fitted model of class BlisClass (extending standard `mirt`'s `SingleGroupClass`).

coef(fitted_blis, IRTpars = TRUE, printSE = TRUE) # SE instead of CI
```

---

gDiscrim *Compute generalized item discrimination*

Description

Generalized version of discrimination index ULI. The function enumerates the ability of an item to distinguish between individuals from upper (U) vs. lower (L) ability groups, i.e. between respondents with high vs. low overall score on the test. Number of groups, as well as upper and lower groups can be specified by user. You can also manually supply the maximal and minimal scores when the theoretical range of item score is known. Note that if the *observed* item range is zero NaN is returned.

Usage

```
gDiscrim(Data, k = 3, l = 1, u = 3, maxscore, minscore, x, ...)
```

Arguments

Data	matrix or data.frame of items to be examined. Rows represent respondents, columns represent items.
k	numeric: number of groups to which may be Data divided by the total score. Default value is 3. See **Details**.
l	numeric: lower group. Default value is 1. See **Details**.
u	numeric: upper group. Default value is 3. See **Details**.
maxscore	numeric: maximal score in ordinal items. If missing, vector of obtained maximal scores is imputed. See **Details**.
minscore	numeric: minimal score in ordinal items. If missing, vector of obtained minimal scores is imputed. See **Details**.
x	deprecated. Use argument Data instead.
...	Arguments passed on to base::findInterval
	rightmost.closed logical; if true, the rightmost interval, vec[N-1] .. vec[N] is treated as *closed*, see below.

`all.inside` logical; if true, the returned indices are coerced into `1,...,N-1`, i.e., `0` is mapped to `1` and `N` to `N-1`.

`left.open` logical; if true all the intervals are open at left and closed at right; in the formulas below, $\leq$ should be swapped with $<$ (and $>$ with $\geq$), and `rightmost.closed` means 'leftmost is closed'. This may be useful, e.g., in survival analysis computations.

`checkSorted` logical indicating if `vec` should be checked, i.e., `is.unsorted(vec)` is asserted to be false. Setting this to `FALSE` skips the check gaining speed, but may return nonsense results in case `vec` is not sorted.

`checkNA` logical indicating if each `x[i]` should be checked as with `is.na(.)`. Setting this to `FALSE` in case of `NA`'s in `x[]` may result in platform dependent nonsense.

Details

The function computes total test scores for all respondents and then divides the respondents into `k` groups. The lower and upper groups are determined by `l` and `u` parameters, i.e., l-th and u-th group where the ordering is defined by increasing total score.

In ordinal items, difficulty is calculated as difference of average score divided by range (maximal possible score `maxscore` minus minimal possible score `minscore` for given item).

Discrimination is calculated as difference in difficulty between upper and lower group.

Note

`gDiscrim` is used by `DDplot()` function.

get_orig_levels *Get Original Levels from a Fitted BLIS model*

Description

Just a simple accessor to original levels and correct key stored in fitted BLIS model.

Usage

```
get_orig_levels(object)
```

Arguments

object	*object of class BlisClass*, model fitted via `fit_blis()` or `blis()`.

Value

list of the original levels and correct key. Key is stored as an attribute `key` for every individual item.

See Also

Other BLIS/BLIRT related: BlisClass-class, coef,BlisClass-method, fit_blis(), nominal_to_int(), obtain_nrm_def(), print.blis_coefs()

Examples

```
fit <- fit_blis(HCItest[, 1:20], HCIkey)
get_orig_levels(fit)
```

ggWrightMap *Plot person-item map (Wright map) using* ggplot2

Description

This function allows to generate Wright map (also called person-item map) using `ggplot()` function from the **ggplot2** package. Wright map is used to jointly display histogram of abilities (or other measured trait) and item difficulty parameters. Function takes pre-estimated parameter estimates, such as those obtained from an IRT model.

Usage

```
ggWrightMap(
  theta,
  b,
  binwidth = 0.5,
  color = "blue",
  size = 15,
  item.names,
  ylab.theta = "Respondent latent trait",
  ylab.b = "Item difficulty",
  rel_widths = c(1, 1)
)
```

Arguments

`theta`	numeric: vector of ability estimates.
`b`	numeric: vector of difficulty estimates.
`binwidth`	numeric: the width of the bins of histogram.
`color`	character: color of histogram.
`size`	text size in pts.
`item.names`	names of items to be displayed.
`ylab.theta`	character: description of y-axis for the histogram.
`ylab.b`	character: description of y-axis for the plot of difficulty estimates.
`rel_widths`	numeric: vector of length 2 specifying ratio of "facet's" widths.

GMAT *Dichotomous dataset based on GMAT with the same total score distribution for groups.*

Description

The GMAT is a generated dataset based on parameters from Graduate Management Admission Test (GMAT, Kingston et al., 1985). First two items were considered to function differently in uniform

and non-uniform way respectively. The dataset represents responses of 2,000 subjects to multiple-choice test of 20 items. A correct answer is coded as 1 and incorrect answer as 0. The column `group` represents group membership, where 0 indicates reference group and 1 indicates focal group. Groups are the same size (i.e. 1,000 per group). The distributions of total scores (sum of correct answers) are the same for both reference and focal group (Martinkova et al., 2017). The column `criterion` represents generated continuous variable which is intended to be predicted by test.

Usage

```
GMAT
```

Format

A `GMAT` data frame consists of 2,000 observations on the following 22 variables:

Item1-Item20 dichotomously scored items of the test

group group membership vector, `"0"` reference group, `"1"` focal group

criterion continuous critetion intended to be predicted by test

HCI *Homeostasis Concept Inventory dichotomous dataset*

Description

HCI dataset consists of the dichotomously scored responses of 651 students (405 males, 246 females) to Homeostasis Concept Inventory (HCI) multiple-choice test. It contains 20 items, vector of gender membership and identificator whether students plan to major in life sciences.

Usage

```
HCI
```

Format

HCI is a data.frame consisting of 651 observations on the 22 variables.

Item1-Item20 Dichotomously scored items of the HCI test.

gender Gender membership, "0" males, "1" females.

major Identificator whether student plans to major in the life sciences.

total Total score

HCIdata *Homeostasis concept inventory full dataset*

Description

HCIdata dataset consists of the responses of 669 students (405 males, 246 females, 18 without gender specification) to Homeostasis Concept Inventory (HCI) multiple-choice test. It contains answers to 20 multiple-choice items, scored items, total score, gender membership, identifier whether students plan to major in science, study year, minority membership, identifier whether English is the student's first language, and type of school.

Usage

```
HCIdata
```

Format

HCIdata is a data.frame consisting of 669 observations on the 47 variables.

A1-A20 Multiple-choice items of the HCI test.

QR1-QR20 Scored items of the HCI test, "0" incorrect, "1" correct.

total Total test score.

gender Gender membership, "M" males, "F" females, "none" undisclosed.

major Identifier whether students plans to major in the life sciences.

yearc5 Study year.

minority Minority membership, "maj" majority, "min" Black/Hispanic minority, "none" undisclosed.

EnglishF Identifier whether English is the student's first language.

typeS Course type, "allied" allied health, "majors" physiology courses for science majors, "mixed majors" courses for non-majors.

typeSCH Type of school, "AC" associate's college, "BCAS" baccalaureate college: arts and sciences focus, "R1" research university, "MCU" master's college and university.

`HCIgrads` *Homeostasis concept inventory dataset of graduate students*

Description

`HCIgrads` dataset consists of the responses of 10 graduate students to Homeostasis Concept Inventory (HCI) multiple-choice test. It contains answers to 20 multiple-choice items, scored items, and total test score.

Usage

```
HCIgrads
```

Format

`HCIgrads` is a `data.frame` consisting of 10 observations on the 42 variables.

A1-A20 Multiple-choice items of the HCI test.

QR1-QR20 Scored items of the HCI test, `"0"` incorrect, `"1"` correct.

total Total test score.

HCItestretest *Homeostasis concept inventory test-retest dataset*

Description

HCItestretest dataset consists of the responses of 45 students to Homeostasis Concept Inventory (HCI). It contains answers to 20 multiple-choice items, scored items, identifier of test/retest, total score, gender membership and identifier whether students plan to major in life sciences. The data are organized so that each pair of subsequent rows belongs to one student. Students took no courses on homeostasis between the test and retest.

Usage

```
HCItestretest
```

Format

HCItestretest is a data.frame consisting of 90 observations on the 44 variables.

A1-A20 Multiple-choice items of the HCI test.

QR1-QR20 Scored items of the HCI test, "0" incorrect, "1" correct.

test Identifier of test vs retest, "test" test, "retest" retest after.

total Total test score.

gender Gender membership, "M" male, "F" female.

major Identifier whether student plans to major in the life sciences.

`HeightInventory` *Height inventory dataset*

Description

`HeightInventory` dataset consists of the responses of 4,885 respondents (1479 males, 3406 females) to a Height Inventory (Rečka, 2018). It contains 26 ordinal items of self-perceived height rated on a scale `"1"` strongly disagree, `"2"` disagree, `"3"` agree, `"4"` strongly agree, vector of self-reported heights (in centimeters), and vector of gender membership. Total score is included as the last variable, total score is NA for respondents who missed any item.

Usage

```
HeightInventory
```

Format

`HeightInventory` is a `data.frame` consisting of 4,885 observations on the 28 variables. First 26 variables are responses on scale `"1"` strongly disagree, `"2"` disagree, `"3"` agree, `"4"` strongly agree. Items 14 - 26 were reverse-coded, so that all items are scored in the same direction. Names of these items start with `"R-"`. Original item number and English wording is provided below.

ShortTrousers 1. A lot of trousers are too short for me.

TallerThanM 2. I am taller than men of my age.

TallerThanF 3. I am taller than women of my age.

HeightForBasketball 4. I have an appropriate height for playing basketball or volleyball.

AskMeToReach 5. Other people sometimes ask me to reach something for them.

CommentsTall 6. I am used to hearing comments about how tall I am.

ConcertObstructs 7. At concerts, my stature usually obstructs other people's views.

ShortBed 8. Ordinary beds are too short for me.

TopShelfEasy 9. I can easily take wares from top shelves at a store.

CrowdViewComf 10. In a crowd of people, I still have a comfortable view.

ShortBlanket 11. Blankets and bedspreads rarely cover me completely.

BendToHug 12. When I want to hug someone, I usually need to bend over.

CarefulHead 13. I must often be careful to avoid bumping my head against a doorjamb or a low ceiling.

R-SmallerThanM 14. I am smaller than men of my age. (reversed)

R-StoolNeeded 15. I often need a stool to reach something other people could reach without one. (reversed)

R-PlayDwarf 16. I could play a dwarf. (reversed)

R-SmallerThanW 17. I am smaller than women of my age. (reversed)

R-NoticeSmall 18. One of the first things people notice about me is how small I am. (reversed)

R-OnTipToes 19. I often need to stand on the tip of my toes to get a better view. (reversed)

R-ClothChildSize 20. When I buy clothes, children's sizes often fit me well. (reversed)

R-BusLegsEnoughSpace 21. I have enough room for my legs when traveling by bus. (reversed)

R-FasterWalk 22. I often need to walk faster than I'm used to in order to keep pace with taller people. (reversed)

R-AgeUnderestim 23. Because of my smaller stature, people underestimate my age. (reversed)

R-WishLowerChair 24. It would be more comfortable for me if chairs were made lower. (reversed)

R-UpwardLook 25. When talking to other adults, I have to look upwards if I want to meet their eyes. (reversed)

R-MirrorTooHigh 26. Some mirrors are placed so high up that I have to crane my neck to use them. (reversed)

gender Gender membership, `"M"` males, `"F"` females.

HeightCM Self-reported height in centimeters.

total Total score.

Note

Thanks to Karel Rečka and Hynek Cígler for sharing this dataset.

`ICCrestricted` *Range-restricted reliability with intra-class correlation*

Description

Function estimating reliability with intra-class correlation for the complete or for the range-restricted sample.

Usage

```
ICCrestricted(
  Data,
  case,
  var,
  rank = NULL,
  dir = "top",
  sel = 1,
  nsim = 100,
  ci = 0.95,
  seed = NULL
)
```

Arguments

Data	matrix or data.frame which includes variables describing ID of ratees (specified in case), ratings (specified in var), and (optionally) rank of ratees (specified in rank).
case	character: name of the variable in Data with ID of the ratee (subject or object being evaluated, such as a respondent, proposal, patient, applicant etc.)
var	character: name of the variable in Data with the ratings/scores.
rank	numeric: vector of ranks of ratees. If not provided, rank of ratee is calculated based on average rating based on var variable.
dir	character: direction of range-restriction, available options are "top" (default) or "bottom". Can be an unambiguous abbreviation (i.e., "t" or "b").
sel	numeric: selected number (given > 1) or percentage (given <= 1) of ratees. Default value is 1 (complete dataset).
nsim	numeric: number of simulations for bootstrap confidence interval. Default value is 100.
ci	numeric: confidence interval. Default value is 0.95.
seed	seed for simulations. Default value is NULL, random seed. See lme4::bootMer() for more detail.

Value

A data.frame with the following columns:

n_sel	number of ratees selected/subsetted.
prop_sel	proportion of ratees selected.
dir	direction of range-restriction. NA if range is effectively not restricted (100% used).
VarID	variance due to ratee, "true variance", between-group variance.
VarResid	residual variance.
VarTotal	total variance.
ICC1	single-rater inter-rater reliability.
ICC1_LCI	lower bound of the confidence interval for ICC1.
ICC1_UCI	upper bound of the confidence interval for ICC1.
ICC3	multiple-rater inter-rater reliability.
ICC3_LCI	lower bound of the confidence interval for ICC3.
ICC3_UCI	upper bound of the confidence interval for ICC3.

Erosheva, E., Martinkova, P., & Lee, C. (2021b). Supplementary material for When zero may not be zero: A cautionary note on the use of inter-rater reliability in evaluating grant peer review.

Examples

```
# ICC for the whole sample
ICCrestricted(Data = AIBS, case = "ID", var = "Score", rank = "ScoreRankAdj")

# ICC for the range-restricted sample considering 80% of top ratees
ICCrestricted(
  Data = AIBS, case = "ID", var = "Score", rank = "ScoreRankAdj",
  sel = 0.8
)
```

ItemAnalysis *Compute traditional item analysis indices*

Description

Computes various traditional item analysis indices including difficulty, discrimination and item validity. For ordinal items, the function returns scaled values for some of the indices. See the details below.

Usage

```
ItemAnalysis(
  Data,
  minscore = NULL,
  maxscore = NULL,
  cutscore = NULL,
  criterion = NULL,
  k = NULL,
  l = NULL,
  u = NULL,
  bin = "deprecated"
)
```

Arguments

Data	*matrix* or *data.frame* of items to be examined. Rows represent respondents, columns represent items.

`minscore`, `maxscore`
: *integer*, theoretical minimal/maximal score. If not provided, these are computed on observed data. Automatically recycled to the number of columns of the data.

`cutscore`
: *integer* If provided, the input data are binarized accordingly. Automatically recycled to the number of columns of the data.

`criterion`
: vector of criterion values.

`k`, `l`, `u`
: Arguments passed on to `gDiscrim()`. Provide these if you want to compute generalized upper-lower index along with a standard ULI (using `k` = 3, `l` = 1, `u` = 3), which is provided by default.

`bin`
: *deprecated*, use `cutscore` instead. See the **Details**.

Details

For calculation of generalized ULI index, it is possible to specify a custom number of groups `k`, and which two groups `l` and `u` are to be compared.

In ordinal items, difficulty is calculated as difference of average score divided by range (maximal possible score `maxscore` minus minimal possible score `minscore`).

If `cutscore` is provided, item analysis is conducted on binarized data; values greater or equal to cut-score are set to `1`, other values are set to `0`. Both the `minscore` and `maxscore` arguments are then ingored and set to 0 and 1, respectively.

Value

A `data.frame` with following columns:

`Difficulty`
: average score of the item divided by its range.

`Mean`
: average item score.

`SD`
: standard deviation of the item score.

`Cut.score`
: cut-score specified in `cutscore`.

`obs.min`
: observed minimal score.

`Min.score`
: minimal score specified in `minscore`; if not provided, observed minimal score.

`obs.max`
: observed maximal score.

`Max.score`
: maximal score specified in `maxscore`; if not provided, observed maximal score.

`Prop.max.score`
: proportion of maximal scores.

`RIT`
: item-total correlation (correlation between item score and overall test score).

`RIR`
: item-rest correlation (correlation between item score and overall test score without the given item).

`ULI`
: upper-lower index using the standard parameters (3 groups, comparing 1st and 3rd).

`Corr.criterion`
: correlation between item score and criterion `criterion`.

`gULI`
: generalized ULI. `NA` when the arguments `k`, `l`, and `u` were not provided.

`Alpha.drop`
: Cronbach's alpha without given item.

`Index.rel`
: Gulliksen's (1950) item reliability index.

`Index.val`	Gulliksen's (1950) item validity index.
`Perc.miss`	Percentage of missed responses on the particular item.
`Perc.nr`	Percentage of respondents that did not reached the item nor the subsequent ones, see `recode_nr()` for further details.

`LearningToLearn` *Dichotomous dataset of learning to learn test*

Description

`LearningToLearn` is a real longitudinal dataset used in Martinkova et al (2020) study, demonstrating differential item functioning in change (DIF-C) on Learning to Learn (LtL) test. Among other variables, it primarily contains binary-coded responses of 782 subjects to (mostly) multiple-choice test consisting of 41 items within 7 subscales (see **Format** for details). Each respondent was tested twice in total – the first time in Grade 6 and the second time in Grade 9. Most importantly, school track (variable `track_01` or `track`) is available, with 391 students attending basic school (BS) and 391 pursuing selective academic school (AS). This dataset was created using propensity score matching algorithm to achieve similar characteristics in both tracks (see **References** for details). To further simplify the work with `LtL` dataset, we provide computed total scores as well as 7 subscores, both for Grade 6 and Grade 9. The dataset also includes *change* variables for each item (see **Format** for details) for more detailed DIF-C analysis using multinomial regression model.

Usage

```
LearningToLearn
```

Format

A `LearningToLearn` data frame consists of 782 observations on the following 141 variables:

track_01 Dichotomously scored school track, where `"1"` denotes the selective academic school one.

track School track, where `"AS"` represents the selective academic school track, and `"BS"` stands for basic school track.

score_6 & score_9 Total test score value obtained by summing all 41 items of `LtL`, the number denotes the Grade which the respondent was taking at the time of testing.

score_6_subtest1–score_6_subtest7 Scores of respective cognitive subtest (1–7) of `LtL` in Grade 6.

score_9_subtest1–score_9_subtest7 Scores of respective cognitive subtest (1–7) of `LtL` in Grade 9.

Item1A_6–Item7F_6 Dichotomously coded 41 individual items obtained at Grade 6, `"1"` represents the correct answer to the particular item.

Item1A_9–Item7F_9 Dichotomously coded 41 individual items obtained at Grade 9, `"1"` represents the correct answer to the particular item.

Item1A_changes–Item7F_changes Change patterns with those possible values:

- a student responded correctly in neither Grade 6 nor in Grade 9 (did not improve, `"00"`)
- a student responded correctly in Grade 6 but not in Grade 9 (deteriorated, `"10"`)
- a student did not respond correctly in Grade 6 but responded correctly in Grade 9 (improved, `"01"`), and
- a student responded correctly in both grades (did not deteriorate, `"11"`)

`MSATB` *Dichotomous dataset of Medical School Admission Test in Biology.*

Description

The `MSATB` dataset consists of the responses of 1,407 subjects (484 males, 923 females) to admission test to medical school in the Czech republic. It contains 20 selected items from original test while first item was previously detected as differently functioning (Vlckova, 2014). A correct answer is coded as 1 and incorrect answer as 0. The column `gender` represents gender of students, where 0 indicates males (reference group) and 1 indicates females (focal group).

Usage

```
MSATB
```

Format

A `MSATB` data frame consists of 1,407 observations on the following 21 variables:

Item dichotomously scored items of the test

gender gender of respondents, `"0"` males, `"1"` females

NIH *NIH grant peer review scoring dataset*

Description

The NIH dataset (Erosheva et al., 2020a) was sampled from a full set of 54,740 R01 applications submitted by black and white principal investigators (PIs) and reviewed by Center for Scientific Review (CSR) of the National Institutes of Health (NIH) during council years 2014–2016.

It contains the original random sample of white applicants as generated by Erosheva et al. (2020b) and a sample of 46 black applicants generated to obtain the same ratio of white and black applicants as in the original sample (for details, see Erosheva et al., 2021a). The dataset was used by Erosheva et al. (2021b) to demonstrate issues of inter-rater reliability in case of restricted samples.

The available variables include preliminary criterion scores on Significance, Investigator, Innovation, Approach, Environment and a preliminary Overall Impact Score. Each of these criteria and the overall score is scored on an integer scale from 1 (best) to 9 (worst). Besides the preliminary criteria and Overall Impact Scores, the data include applicant race, the structural covariates (PI ID, application ID, reviewer ID, administering institute, IRG, and SRG), the matching variables – gender, ethnicity (Hispanic/Latino or not), career stage, type of academic degree, institution prestige (as reflected by the NIH funding bin), area of science (as reflected by the IRG handling the application), application type (new or renewal) and status (amended or not) – as well as the final overall score. In addition, the file includes a study group ID variable that refers to the Matched and Random subsets used in the original study.

Usage

```
NIH
```

Format

NIH is a data.frame consisting of 5802 observations on 27 variables.

ID Proposal ID.

Score Preliminary Overall Impact score (1-9 integer scale, 1 best).

Significance, Investigator, Innovation, Approach, Environment Preliminary Criterion Scores (1-9 integer scale, 1 best).

PIRace Principal investigator's self-identified race; "White" or "Black".

PIID Anonymized ID of principal investigator (PI).

PIGender PI's gender membership; "Male" or "Female".

PIEthn PI's ethnicity; "Hispanic/Latino" or "Non-Hispanic".

PICareerStage PI's career stage; "ESI" Early Stage Investigator, "Experienced" Experienced Investigator, or "Non-ES NI" Non-Early Stage New Investigator.

PIDegree PI's degree; "PhD", "MD", "MD/PhD", or "Others".

PIInst Lead PI's institution's FY 2014 total institution NIH funding; 5 bins with 1 being most-funded.

GroupID Group ID.

RevID Reviewer's ID.

IRG IRG (Integrated Research Group) id.

AdminOrg Administering Organization id.

SRG SRG (Scientific Research Group) id.

PropType Application type, `"New"` or `"Renewal"`.

Ammend Ammend. Logical.

ScoreAvg Average of the three overall scores from different reviewers.

ScoreAvgAdj Average of the three overall scores from different reviewers, increased by multiple of 0.001 of the worst score.

ScoreRank Project rank calculated based on `ScoreAvg`.

ScoreRankAdj Project rank calculated based on `ScoreAvgAdj`.

ScoreFinalChar Final Overall Impact score (1-9 integer scale, 1 best; `"ND"` refers to "not discussed")

ScoreFinal Final Overall Impact score (1-9 integer scale, 1 best).

`ICCrestricted()`

`nominal_to_int` *Turn nominal (factor) data to integers, keep original levels with a key of correct responses alongside*

Description

Convert a `data.frame` or `tibble` with factor variables (items) to integers, keeping the original factor levels (i.e. response categories) and correct answers (stored as an `key` attribute of each item) alongside.

Usage

```
nominal_to_int(Data, key)
```

Arguments

Data	*data.frame* or *tibble* with all columns being factors. Support for *matrix* is limited and behavior not guaranteed.
key	A single-column `data.frame`, (**not** matrix) `tibble` or - preferably - a factor vector of levels considered as correct responses.

Details

Fitting a nominal model using `mirt::mirt()` package requires the dataset to consist only of integers, *arbitrarily* representing the response categories. You can convert your dataset to integers on your own in that case.

On the other hand, BLIS model (and thus also the BLIRT parametrization) further requires the information of correct item response category. On top of that, the same information is leveraged when fitting a `mirt` model that conserves the "directionality" of estimated latent ability (using a model definition from `obtain_nrm_def()`). In these cases, you are recommended to use `nominal_to_int()` (note that `fit_blis()` and `blis()` does this internally). Note also that fitted BLIS model (of class BlisClass) stores the original levels with correct answer key in its `orig_levels` slot, accessible by a user via `get_orig_levels()`.

Value

List of original levels with logical attribute `key`, which stores the information on which response (level) is considered correct. *Note that levels not used in the original data are dropped.*

See Also

Other BLIS/BLIRT related: `BlisClass-class`, `coef,BlisClass-method`, `fit_blis()`, `get_orig_levels()`, `obtain_nrm_def()`, `print.blis_coefs()`

---

obtain_nrm_def *Obtain model definition for* `mirt`*'s nominal model taking in account the key of correct answers*

Description

Standard `mirt` model with `itemtype = "nominal"` puts the identification constrains on the item response category slopes such as $ak_0 = 0$ and $ak_{(K-1)} = (K-1)$, freely estimating the rest.

While nominal item responses are unordered by definition, it is often the case that one of the item response categories is correct and the respondents endorsing this category "naturally" possess a higher latent ability. Use this function to obtain model definition where the correct response category k_c for item i with K possible response categories translates to constrains $ak_{k_c} = (K-1)$ and $ak_{k_{d1}} = 0$, with k_{d1} being the first incorrect response category (i.e. the first distractor).

Usage

```
obtain_nrm_def(data_with_key, ...)
```

Arguments

data_with_key	The output of nominal_to_int().
...	arguments passed onto mirt::mirt(). No practical use for now.

Value

A data.frame with the starting values, parameter numbers, estimation constrains etc. Pass it as pars argument of mirt::mirt().

See Also

Other BLIS/BLIRT related: BlisClass-class, coef,BlisClass-method, fit_blis(), get_orig_levels(), nominal_to_int(), print.blis_coefs()

Examples

```
library(mirt)

# convert nominal data to integers and the original labels with correct answers
data_with_key <- nominal_to_int(HCItest[, 1:20], HCIkey)

# build model definition for {mirt} using the returned list from above
nrm_def <- obtain_nrm_def(data_with_key)

# fit the nominal model using the obtained model definition in `pars` argument
fit <- mirt(data_with_key$Data, 1, "nominal", pars = nrm_def)
```

---

plot.sia_parallel *Plot Method for Parallel Analysis Output*

Description

You can call this method to plot an existing object resulting from fa_paralell() function, which behaves as a standard data.frame, but can be automatically recognized and processed with a dedicated plot method. Also, you can *post-hoc* disable the Kaiser boundaries shown by default.

Usage

```
## S3 method for class 'sia_parallel'
plot(x, y, ...)
```

Arguments

x	object of class sia_parallel to plot.
y	*ignored*
...	additional argument:
	show_kaiser *logical*, whether to show horizonal lines denoting Kaiser boundaries (eigenvalue 0 and/or 1 for FA and/or PCA, respectively). Defaults to TRUE.

Examples

```
## Not run:
fa_parallel_result <- BFI2[, 1:60] |> fa_parallel(plot = FALSE) # without plot
fa_parallel_result |> plot() # generate plot from "fitted" object
fa_parallel_result |> plot(show_kaiser = FALSE) # hide Kaiser boundaries

## End(Not run)
```

---

plotAdjacent *Plot category probabilities of adjacent category logit model*

Description

Function for plotting category probabilities function estimated by vglm() function from the VGAM package using the **ggplot2** package.

Usage

```
plotAdjacent(x, matching.name = "matching")
```

Arguments

x	object of class vglm
matching.name	character: name of matching criterion used for estimation in x.

Value

An object of class ggplot and/or gg.

# adjacent category logit model for item 1
fit <- vglm(Science[, 1] ~ score, family = acat(reverse = FALSE, parallel = TRUE))
# coefficients for item 1
coef(fit)

plotAdjacent(fit, matching.name = "Total score")
```

---

plotCumulative *Plot cumulative and category probabilities of cumulative logit model*

Description

Function for plotting cumulative and category probabilities function estimated by `vglm()` function from the VGAM package using the **ggplot2** package.

Usage

```
plotCumulative(x, type = "cumulative", matching.name = "matching")
```

Arguments

x	object of class vglm
type	character: type of plot to be displayed. Options are "cumulative" (default) for cumulative probabilities and "category" for category probabilities.
matching.name	character: name of matching criterion used for estimation in x.

Value

An object of class ggplot and/or gg.

plotDIFirt *Plot item characteristic curve of DIF IRT model*

Description

Plots characteristic curve of IRT model.

Usage

```
plotDIFirt(
  parameters,
  test = "Lord",
  item = "all",
  item.name,
  same.scale = FALSE
)
```

Arguments

`parameters`	numeric: data matrix or data frame. See **Details**.
`test`	character: type of statistic to be shown. See **Details**.
`item`	either character ("all"), or numeric vector, or single number corresponding to column indicators. See **Details**.
`item.name`	character: the name of item.
`same.scale`	logical: are the item `parameters` on the same scale? (default is "FALSE"). See **Details**.

Details

This function plots characteristic curve of DIF IRT model.

The `parameters` matrix has a number of rows equal to twice the number of items in the data set. The first J rows refer to the item parameter estimates in the reference group, while the last J ones correspond to the same items in the focal group. The number of columns depends on the selected IRT model: 2 for the 1PL model, 5 for the 2PL model, 6 for the constrained 3PL model and 9 for the unconstrained 3PL model. The columns of `irtParam()` have to follow the same structure as the output of `itemParEst()`, `difLord()` or `difRaju()` command from the `difR` package.

Two possible type of `test` statistics can be visualized - `"Lord"` gives only characteristic curves, `"Raju"` also highlights area between these curves.

For default option `"all"`, all characteristic curves are plotted.

```

---

plotDIFLogistic *Function for characteristic curve of 2PL logistic DIF model*

Description

Plots characteristic curve of 2PL logistic DIF model

Usage

```
plotDIFLogistic(x, item = 1, item.name, group.names = c("Reference",
  "Focal"), Data, group, match, draw.empirical = TRUE)
```

Arguments

x	an object of "Logistic" class. See **Details**.
item	numeric: number of item to be plotted
item.name	character: the name of item to be used as title of plot.
group.names	character: names of reference and focal group.
Data	numeric: the data matrix. See **Details**.
group	numeric: the vector of group membership. See **Details**.
match	character or numeric: specifies observed score used for matching. Can be either "score", or numeric vector of the same length as number of observations in Data. See **Details**.
draw.empirical	logical: whether empirical probabilities should be calculated and plotted. Default value is TRUE.

Details

This function plots characteristic curves of 2PL logistic DIF model fitted by `difLogistic()` function from difR package using ggplot2.

`Data` and `group` are used to calculate empirical probabilities for reference and focal group. `match` should be the same as in `x$match`. In case that an observed score is used as a matching variable instead of the total score or the standardized score, `match` needs to be a numeric vector of the same the same length as the number of observations in `Data`.

plotDIFLogistic(x, item = 1, draw.empirical = FALSE)
```

`plotDistractorAnalysis` *Plot item distractor analysis*

Description

Plots graphical representation of item distractor analysis with proportions and optional number of groups.

Usage

```
plotDistractorAnalysis(
  Data,
  key,
  num.groups = 3,
  item = 1,
  item.name,
  multiple.answers = TRUE,
  criterion = NULL,
  crit.discrete = FALSE,
  cut.points,
  data,
  matching,
  match.discrete
)
```

Arguments

`Data`	character: data matrix or data.frame with rows representing unscored item response from a multiple-choice test and columns corresponding to the items.
`key`	character: answer key for the items. The `key` must be a vector of the same length as `ncol(Data)`. In case it is not provided, `criterion` needs to be specified.
`num.groups`	numeric: number of groups to which are the respondents split.
`item`	numeric: the number of the item to be plotted.
`item.name`	character: the name of the item.
`multiple.answers`	logical: should be all combinations plotted (default) or should be answers split into distractors. See **Details**.
`criterion`	numeric: numeric vector. If not provided, total score is calculated and distractor analysis is performed based on it.
`crit.discrete`	logical: is `criterion` discrete? Default value is `FALSE`.
`cut.points`	numeric: numeric vector specifying cut points of `criterion`.
`data`	deprecated. Use argument `Data` instead.
`matching`	deprecated. Use argument `criterion` instead.
`match.discrete`	deprecated. Use argument `crit.discrete` instead.

Details

This function is a graphical representation of the DistractorAnalysis() function. In case that no criterion is provided, the scores are calculated using the item Data and key. The respondents are by default split into the num.groups-quantiles and the proportions of respondents in each quantile are displayed with respect to their answers. In case that criterion is discrete (crit.discrete = TRUE), criterion is split based on its unique levels. Other cut points can be specified via cut.points argument.

If multiple.answers = TRUE (default) all reported combinations of answers are plotted. If multiple.answers = FALSE all combinations are split into distractors and only these are then plotted with correct combination.

plotDistractorAnalysis(Data, key, item = 57, cut.points = seq(10, 96, 10))

## End(Not run)
```

`plotMultinomial` *Plot category probabilities of multinomial model*

Description

Plots category probabilities functions estimated by `multinom()` from the `nnet` package using the **ggplot2** package.

Usage

```
plotMultinomial(x, matching, matching.name = "matching")
```

Arguments

`x`	object of class `multinom`
`matching`	numeric: vector of matching criterion used for estimation in `x`.
`matching.name`	character: name of matching criterion used for estimation in `x`.

Value

An object of class `ggplot` and/or `gg`.

# plotting category probabilities
plotMultinomial(fit, matching, matching.name = "Z-score")
```

---

plot_corr *Compute and plot an item correlation matrix*

Description

Computes and visualizes an item correlation matrix (also known as a heatmap), offering several correlation "types" and optional clustering (with possible cluster outlining). The function relies on ggplot2::ggplot(), providing a high customisability using "the grammar of graphics" (see the examples below).

Usage

```
plot_corr(
  Data,
  cor = c("polychoric", "tetrachoric", "pearson", "spearman", "none"),
  clust_method = "none",
  n_clust = 0L,
  shape = c("circle", "square"),
  labels = FALSE,
  labels_size = 3,
  line_size = 0.5,
  line_col = "black",
  line_alpha = 1,
  fill = NA,
  fill_alpha = NA,
  ...
)
```

Arguments

Data	matrix, data.frame or tibble: either a data.frame with scored items (as columns, one observation per row), or a correlation matrix.
cor	character: correlation "type" used to correlation matrix computation; available options are polychoric, tetrachoric, pearson, spearman, or none (in case you provide the correlation matrix as Data).
clust_method	character: optional clustering method, available options are: ward.D, ward.D2, single, complete, average (= UPGMA), mcquitty (= WPGMA), median (= WPGMC), centroid (= UPGMC) or none (clustering disabled). See hclust() for a detailed description of available options.
n_clust	integer: the number of clusters you want to be outlined. When set to zero (the default), no cluster are outlined, but items still do get sorted according to clust_method (if not set to none).
shape	character: tile appearance; either circle (default) to map the correlation coefficient to circle size and color, or square to draw square-shaped tiles with only shade denoting the coefficient magnitude. You can use an unambiguous abbreviation of the two.
labels	logical: when TRUE, the correlation coefficients are plotted onto tiles.
labels_size	numeric: label size in points (pts).
line_size	numeric: cluster outline width.
line_col	character: color of the outline, either a HEX code (e.g. "#123456"), or one of R's standard colors (see the colors()).
line_alpha	numeric 0-1: the opacity of the outline.
fill	character: the color used to fill the outlined clusters.
fill_alpha	numeric 0–1: the opacity of the fill color.
...	Arguments passed on to psych::polychoric
	correct Correction value to use to correct for continuity in the case of zero entry cell for tetrachoric, polychoric, polybi, and mixed.cor. See the examples for the effect of correcting versus not correcting for continuity.
	smooth if TRUE and if the tetrachoric/polychoric matrix is not positive definite, then apply a simple smoothing algorithm using cor.smooth
	global When finding pairwise correlations, should we use the global values of the tau parameter (which is somewhat faster), or the local values (global=FALSE)? The local option is equivalent to the polycor solution, or to doing one correlation at a time. global=TRUE borrows information for one item pair from the other pairs using those item's frequencies. This will make a difference in the presence of lots of missing data. With very small sample sizes with global=FALSE and correct=TRUE, the function will fail (for as yet undetermined reasons.
	weight A vector of length of the number of observations that specifies the weights to apply to each case. The NULL case is equivalent of weights of 1 for all cases.
	std.err std.err=FALSE does not report the standard errors (faster) deprecated

progress Show the progress bar (if not doing multicores)

ML ML=FALSE do a quick two step procedure, ML=TRUE, do longer maximum likelihood — very slow! Deprecated

delete Cases with no variance are deleted with a warning before proceeding.

max.cat The maximum number of categories to bother with for polychoric.

Details

Correlation heatmap displays selected type of correlations between items. The color of tiles indicates how much and in which way the items are correlated – red color means positive correlation and blue color means negative correlation. Correlation heatmap can be reordered using hierarchical clustering method specified with clust_method argument. When the desired number of clusters (argument n_clust) is not zero and some clustering is demanded, the rectangles outlining the found clusters are drawn.

Value

An object of class ggplot and/or gg.

```
# use first 20 columns from HCI dataset (the remainder are not items)
HCI <- HCI[, 1:20]

# use Pearson product-moment correlation coefficient for matrix computation
plot_corr(HCI, cor = "pearson")

## Not run:
# use tetrachoric correlation and reorder the resulting heatmap
# using Ward's method
HCI |> plot_corr(cor = "tetrachoric", clust_method = "ward.D")

# outline 3 Ward's clusters with bold yellow line and add labels
HCI |>
  plot_corr(
    n_clust = 3, clust_method = "ward.D2", line_col = "yellow",
    line_size = 1.5, labels = TRUE
  )

# add title and position the legend below the plot
library(ggplot2)
```

```
HCI |>
  plot_corr(n_clust = 3) +
  ggtitle("HCI heatmap") +
  theme(legend.position = "bottom")

# mimic the look of corrplot package
plot_corr(HCI, cor = "polychoric", clust_method = "complete", shape = "square") +
  scale_fill_gradient2(
    limits = c(-.1, 1),
    breaks = seq(-.1, 1, length.out = 12),
    guide = guide_colorbar(
      barheight = .8, barwidth = .0275,
      default.unit = "npc",
      title = NULL, frame.colour = "black", ticks.colour = "black"
    )
  ) +
  theme(axis.text = element_text(colour = "red", size = 12))

## End(Not run)
```

`print.blis_coefs` *Print method for BLIS coefficients*

Description

Print method for BLIS coefficients

Usage

```
## S3 method for class 'blis_coefs'
print(x, digits = 3, ...)
```

Arguments

`x`	result of `coef()`.
`digits`	*integer*, number of digits to show in the output. Note that printed object are still an original list, which does not round any value (it is returned invisibly).
`...`	Additional arguments passed on to `print()`.

recode_nr *Recognize and recode not-reached responses*

Description

`recode_nr()` function recognizes and recodes not-reached responses, i.e., missing responses to items such that all subsequent items are missed as well by the respondent.

Usage

```
recode_nr(Data, nr_code = 99, df)
```

Arguments

`Data`	matrix or data.frame: object to be recoded, must include only items columns and no additional information
`nr_code`	single character, integer or numeric: specifying how should be recognized not-reached responses coded (default is `99`)
`df`	deprecated. Use argument `Data` instead.

Value

A `data.frame` object.

```

`ShinyItemAnalysis_options`

Options consulted by ShinyItemAnalysis

Description

The package and interactive {shiny} app consult several options that you can easily set via `options()`. Moreover, there is some behavior that can be changed through environment variables.

Options

Options are set with `options(<option> = <value>)`.

- `sia.disable_modules`: You can completely disable SIA modules by setting this to `TRUE`.
- `sia.modules_repo`: This is the URL for a CRAN-like repository that the app uses to retrieve information about available module packages.
- `sia.offer_modules`: If set to `TRUE` (the default), calling `run_app()` will check for the available SIA modules on the official repository and offer to install those module packages that are not installed yet.

Environment variables

You can set this variable system-wide or use `R` or project-wise `.Renviron` file. For more details, please navigate to the R documentation.

- `SIA_MODULES_DEBUG`: Setting this to `TRUE` provides a verbose description of SIA modules-related processes. Useful only for debugging purposes.
- `SIA_MODULES_FORCE_GUI_INSTALLATION`: When the app is running on shiny-server, interactive module installation within the app is not allowed by default. Setting this variable to `TRUE` will override this restriction and enable module installation in the app.

`startShinyItemAnalysis` *Start ShinyItemAnalysis application*

Description

An interactive shiny application to run test and item analysis. By default, the function runs the application as a background process ("Jobs" tab in the "RStudio" IDE). User is then free to use the R Console for other work and to try the sample R code examples. You can still run the app the usual way in the console by specifying `background = FALSE`.

Usage

```
startShinyItemAnalysis(background = TRUE, ...)

run_app(background = TRUE, ...)
```

Arguments

`background`	*logical*, should the application be run as a background process (in the 'RStudio')?
`...`	Arguments passed on to `utils::install.packages` `lib` character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of `.libPaths()`. `repos` character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as `"https://cloud.r-project.org"`. For more details on supported URL schemes see `url`. Can be `NULL` to install from local files, directories or URLs: this will be inferred by extension from `pkgs` if of length one. `contriburl` URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you mirrored only the 'contrib' section, or only have binary packages. Overrides argument `repos`. Incompatible with `type = "both"`. `method` download method, see `download.file`. `available` a matrix as returned by `available.packages` listing packages available at the repositories, or `NULL` when the function makes an internal call to `available.packages`. Incompatible with `type = "both"`. `destdir` directory where downloaded packages are stored. If it is `NULL` (the default) a subdirectory `downloaded_packages` of the session temporary directory will be used (and the files will be deleted at the end of the session). `dependencies` logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if `repos = NULL`. Can also be a character vector, a subset of `c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")`.

Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.
The default, NA, means c("Depends", "Imports", "LinkingTo").
TRUE means to use c("Depends", "Imports", "LinkingTo", "Suggests") for pkgs and c("Depends", "Imports", "LinkingTo") for added dependencies: this installs all the packages needed to run pkgs, their examples, tests and vignettes (if the package author specified them correctly).
In all of these, "LinkingTo" is omitted for binary packages.

type character, indicating the type of package to download and install. Will be "source" except on Windows and some macOS builds: see the section on 'Binary packages' for those.

configure.args (Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the '--configure-args' flag in the call to R CMD INSTALL. If the character vector has names these are assumed to identify values for '--configure-args' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)
A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for '--configure-args'.

configure.vars (Used only for source installs.) Analogous to configure.args for flag '--configure-vars', which is used to set environment variables for the configure run.

clean a logical value indicating whether to add the '--clean' flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.

Ncpus the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by Sys.getenv("MAKE", "make") accepts argument '-k -j <Ncpus>'.

verbose a logical indicating if some "progress report" should be given.

INSTALL_opts an optional character vector of additional option(s) to be passed to R CMD INSTALL for a source package install. E.g., c("--html", "--no-multiarch", "--no-test-load") or, for macOS, "--dsym".
Can also be a named list of character vectors to be used as additional options, with names the respective package names.

quiet logical: if true, reduce the amount of output. This is *not* passed to available.packages() in case that is called, on purpose.

keep_outputs a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with '.out' appended (overwriting existing files, possibly from previous installation attempts). Alternatively, a character string giv-

ing the directory in which to save the outputs. Ignored when installing from local files.

Value

No return value. Called for side effects.
